

Patient Centred Framework  
for TB programming  
for the development of  
optimized National  
Strategic Plans  
(PCF4NSP)

Kathy Fiekert,  
KNCV Tuberculosis Foundation

# Why do we need a new approach?

The current one is clearly not working ...

- The notification gap is not closing fast enough
- Country strategies are often donor and or theme driven - not evidence
- Available data is not utilised (systematically and correctly)
- Strategies largely concentrate on accelerated case finding & notification - limited consideration of patients' & systems' needs (full package of care)
- Funding allocation is compartmentalised & often inefficient
- Planning ignores stakeholder comparative advantages & complementarity
- Ambitions do not match available resources
- Prioritization overrides optimization
- Patient needs are largely ignored

# Strategic Focus

Close the gaps along the care continuum to find and cure ALL people with TB

Differentiated response by counties to address TB in local contexts

Optimise the implementation of TB services within UHC

Prevent infection, active disease, morbidity and mortality due to TB

Patient-centred approach that promotes quality of care

# The Philosophy

NSP reflects a **patient-centred approach** to planning and **evidence-based prioritisation** of resource allocation to close the gaps along the patient pathway to quality care.

The NSP is operationalised through a **partnership framework** aligned to each **stakeholder's comparative advantage**.

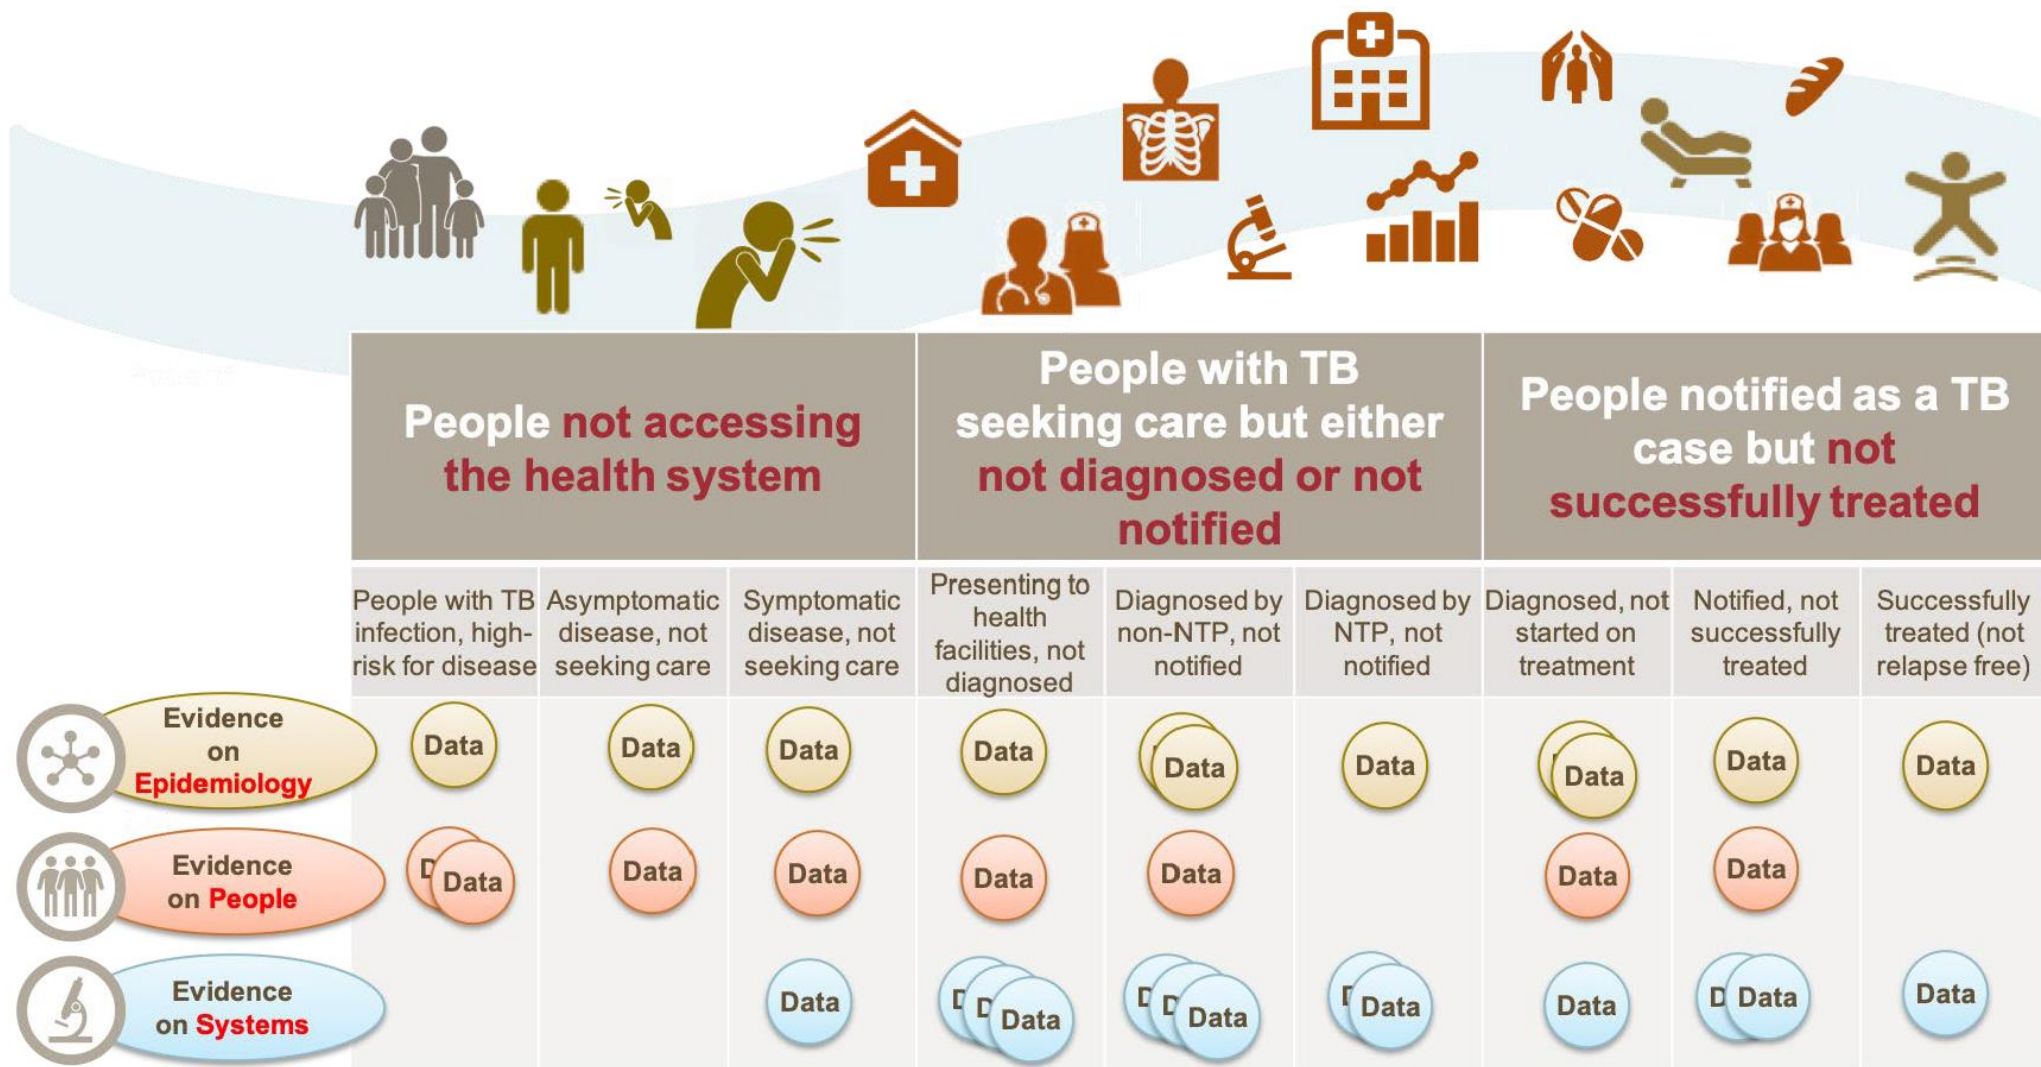

Activities **address systemic and root causes** of the gaps **along the patient pathway**, suggesting the **complementary roles** of sub-national and central governments, departments across the Ministry of Health, partners and other sectors.

### **Additional benefits:**

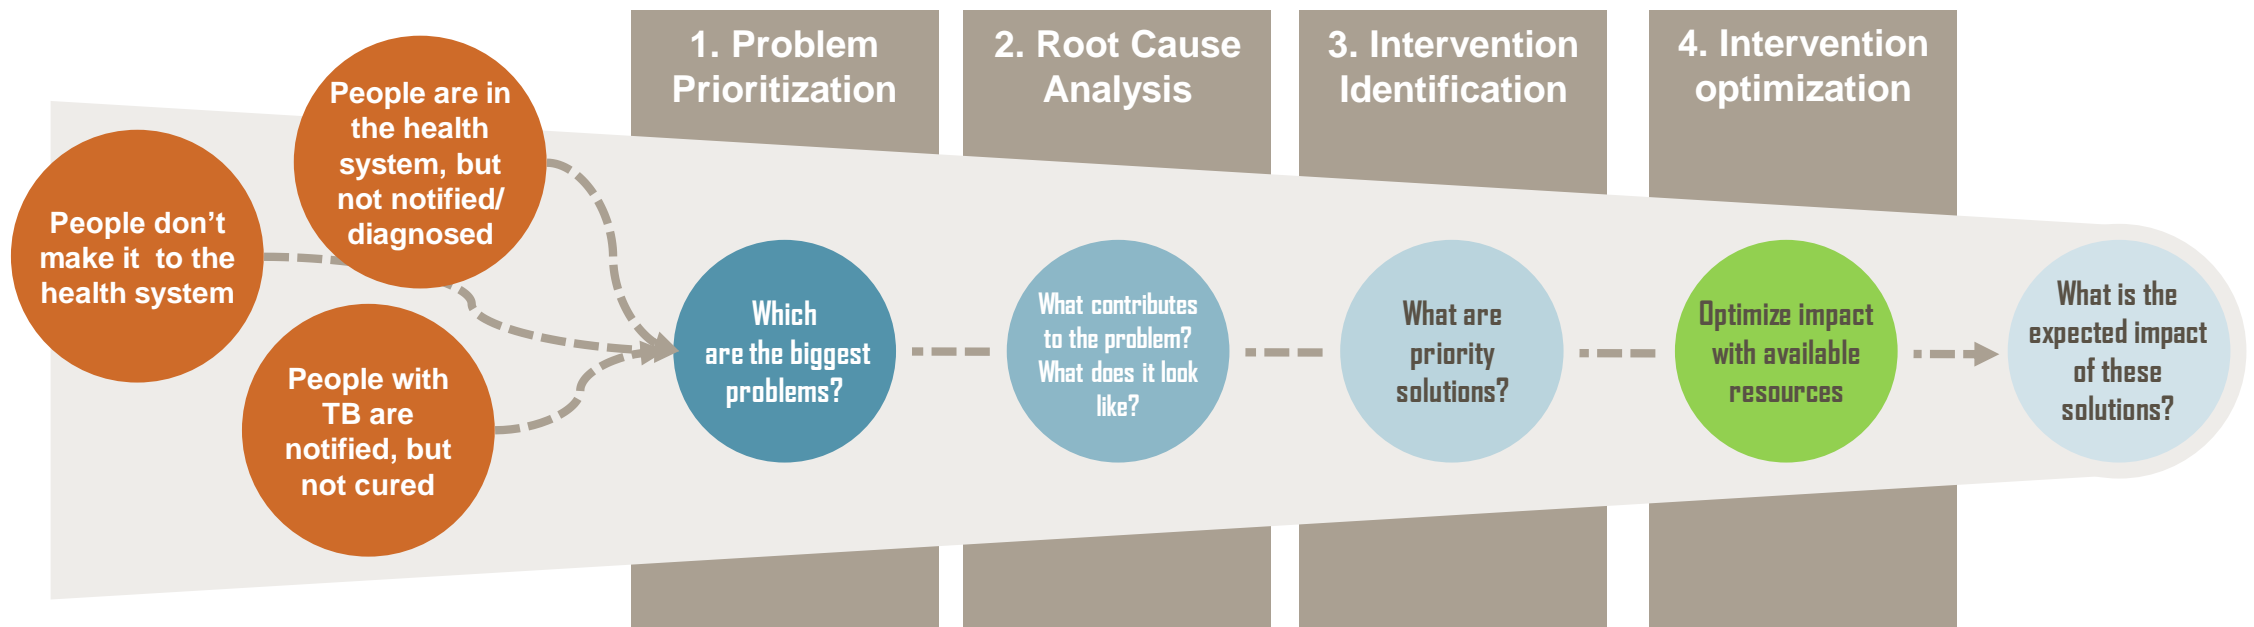

- Countries gain strategic advantage, capacity and a set of tailor-made (country specific) monitoring & planning tools
- Solid framework for evidence based progress monitoring
- Improved stakeholder buy-in, co-ownership and commitment
- Enhanced partner engagement and service delivery/ care network

# Data consolidation along the patient pathway

# Framework for prioritization and planning

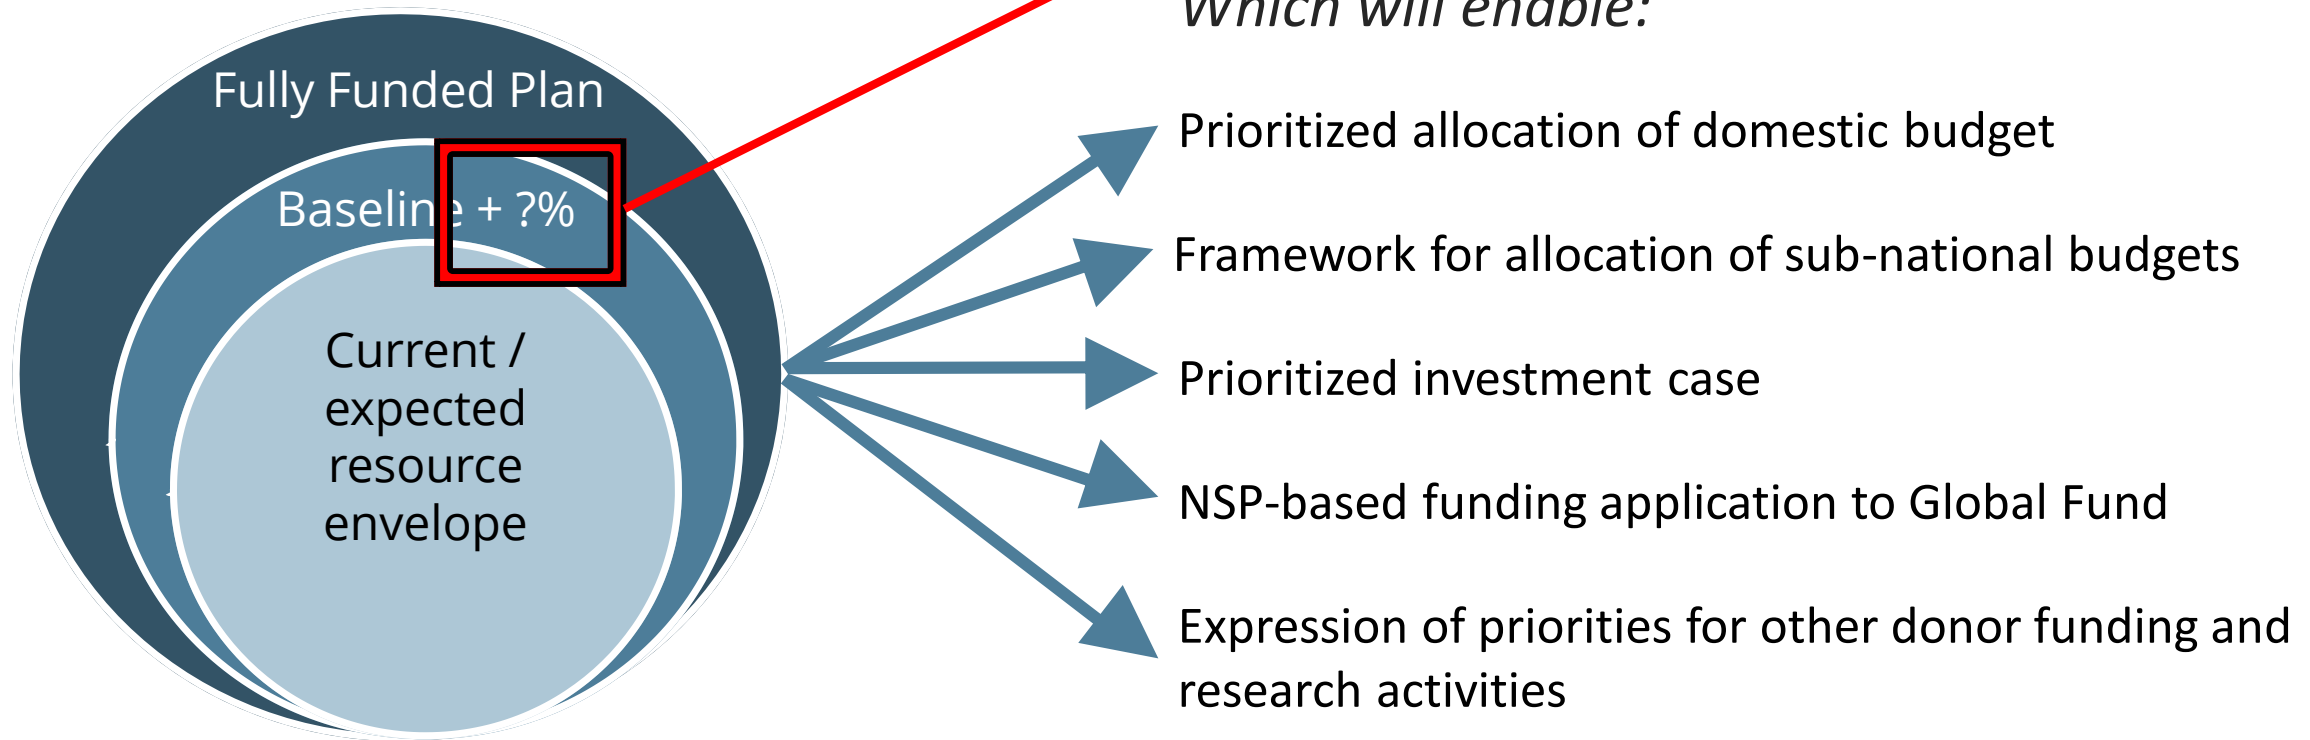

Reviewing the evidence about the biggest **epidemiological challenges** and the biggest **challenges on a patient's pathway to care** can help to identify which sets of problems should be priorities for the national TB programme.

**Aim:** To create a national plan that is prioritized to reflect optimal allocative efficiency given at least 3 funding scenarios: 1) current / expected resource envelope, 2) +?% increase; and 3) fully funded

Acceptable additional resource input vs worthwhile enhancement/ improvement of impact

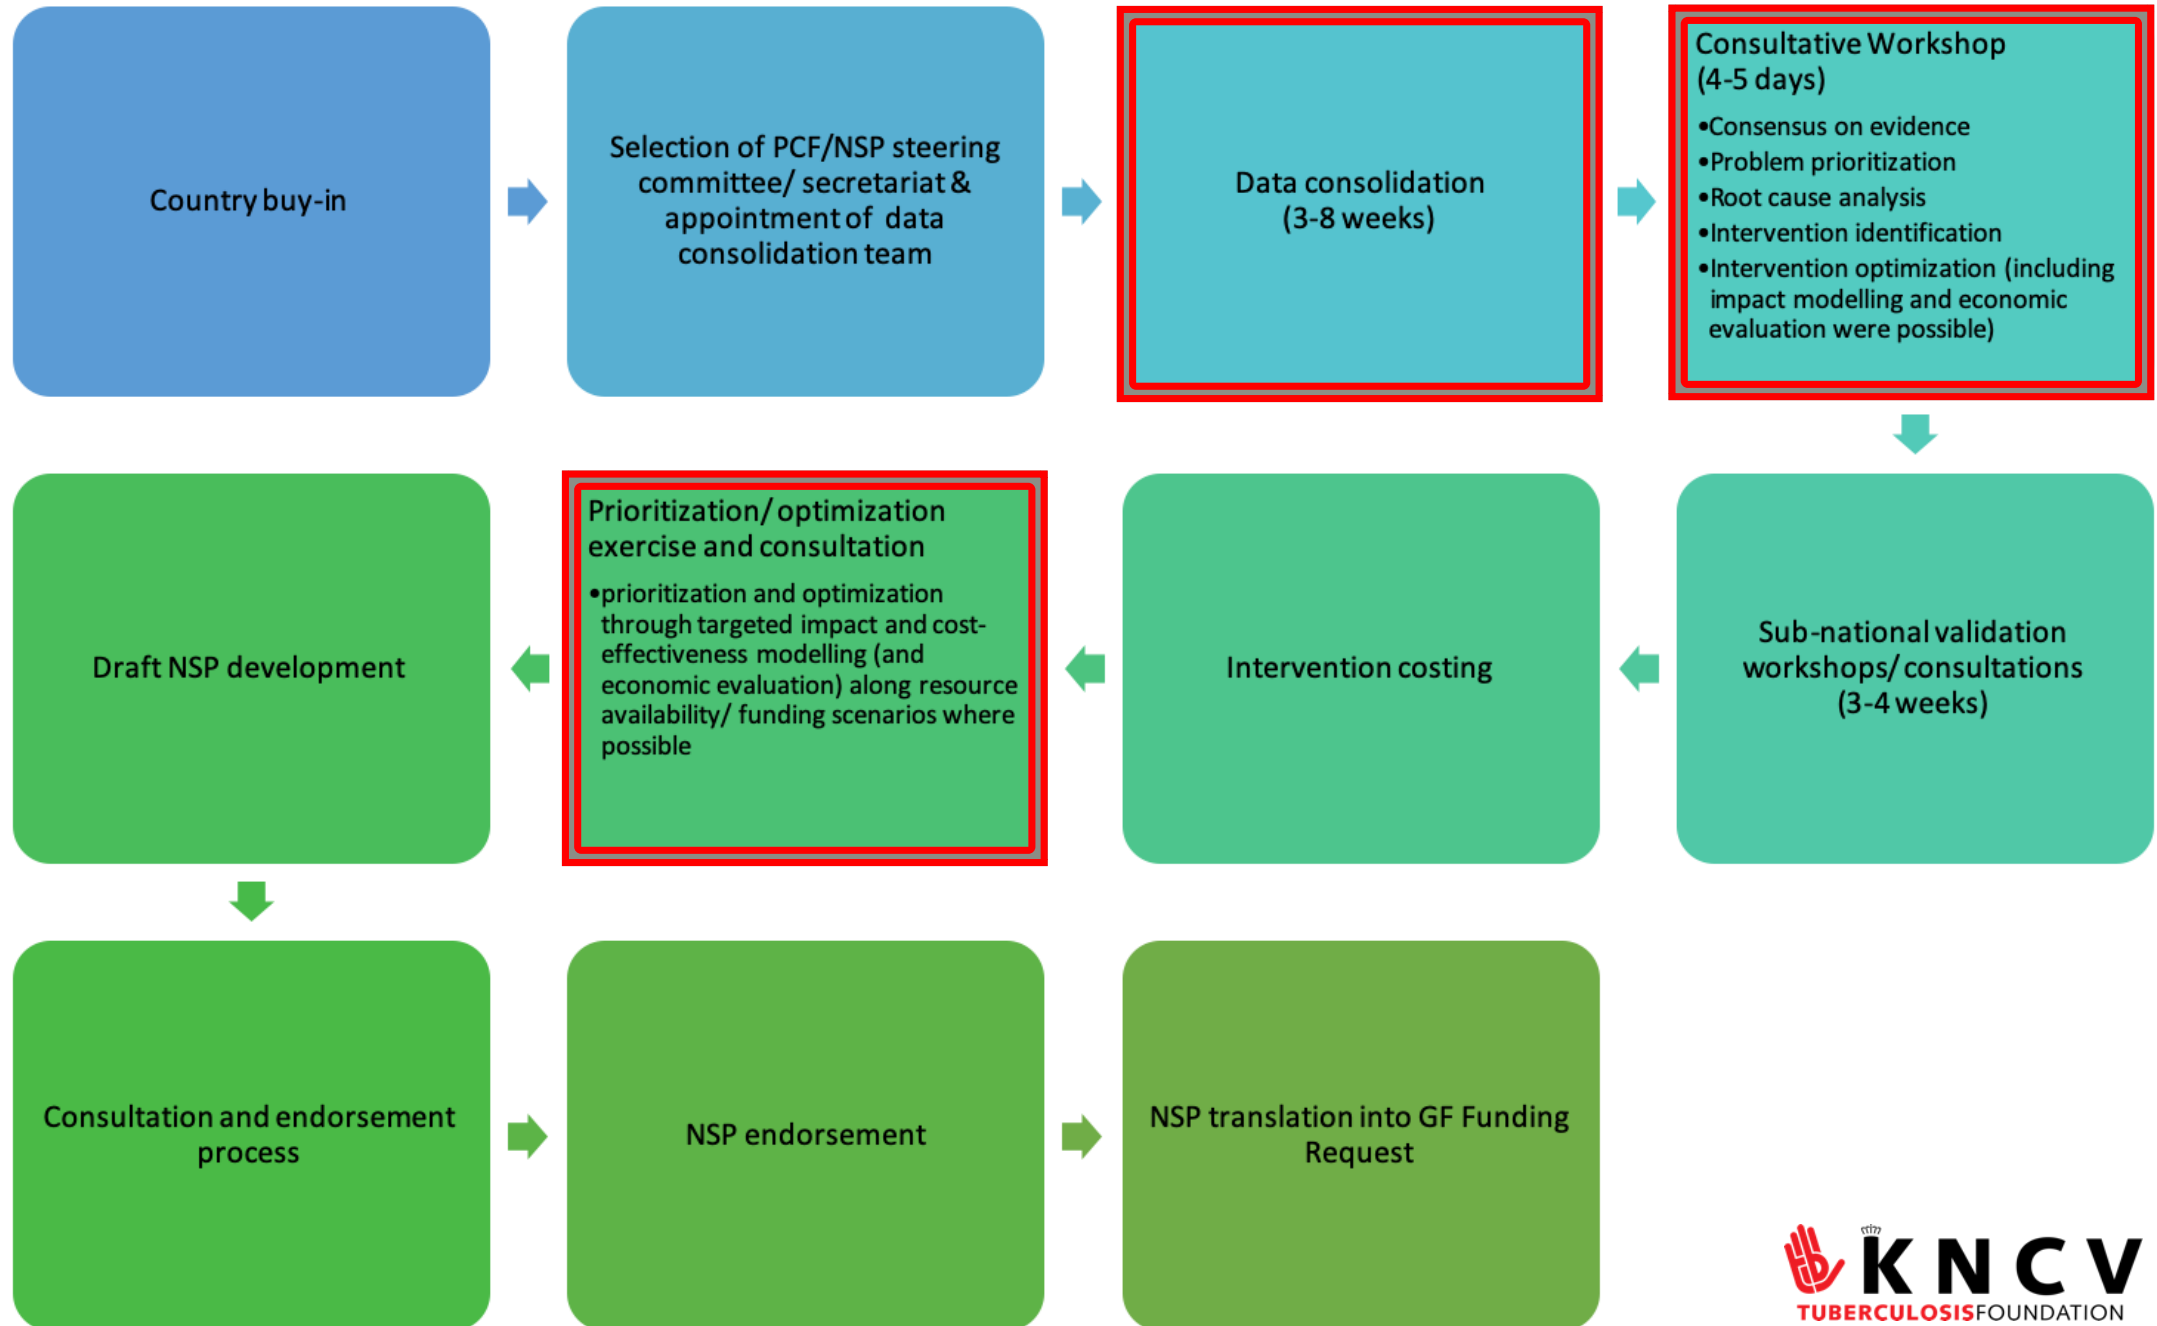

Which will enable:

# The Ask

- By 2021, at least 10 high TB burden countries will have prioritized NSPs that optimize impact given known resources.
- 6 countries will have successfully applied through the GF NSP tailored FR mechanism
- 3 of which will have applied NSP optimization using impact modelling and economic evaluation
- By End 2019 a draft NSP optimization guideline, and toolkit will be available

# Process

## Data and evidence mapped to the care continuum

- Priority setting requires : Know your epidemiology, know your patient, know your system

Patient  System  Epi	People don't make it to the health system				People with TB in the health system, but not notified/diagnosed			People with TB are notified, but not cured		Total
	People with TB infection, high-risk for disease	Asymptomatic disease, not seeking care	Symptomatic disease, not seeking care		Presenting to health facilities, not diagnosed	Diagnosed by non-NTP, not notified	Diagnosed by NTP, not notified	Notified, not durable cure	Durable cure (relapse free)	
		⑤	⑥	DS-TB	①	②				
				DR-TB	③	④				
				TB/HIV						
	Total									

**# Important metrics from available evidence resources (see following slides)**

# Data sources

Evidence on Epidemiology	Evidence on People	Evidence on Systems
TB Prevalence Survey	Patient Pathway Analysis	Service Availability & Readiness Assessment
Drug Resistance Survey	Relevant Policies and other relevant strategic plans and disease and social programmes	Joint Assessment of National Health Strategies and Plans
Surveillance data	Surveys on health seeking behaviour, patient costs, nutrition etc.	Health Expenditure Utilisation Survey
Epidemiological Review	Population driven surveys	Cascade analyses
Mortality studies	Adherence studies	Inventory studies
National Strategic Plan	Joint TB and HIV Program Review	Health Sector Strategic Plan
Global TB Report	Demographic Health Survey	World Social Protection Report
Literature review of published articles, (TA) reports, grey literature		

**Risk of data overload and excessive burden on the system**

## Country Profile data summary sheets

### 2017 EPI REVIEW

Between 2012 and 2016 TB notifications decreased on average by 6% per year from 98,400 to 73,066. The biggest decrease of 10.4% was in 2016, 8,509 cases less than in 2015 (n= 81,575). Since the introduction of GeneXpert there has been a slight increase in the number of bacteriologically confirmed cases but the overall impact on case notifications

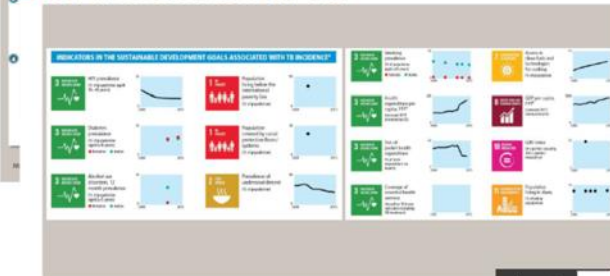

### 2016 PREVALENCE SURVEY

65% of people with TB symptoms had not sought health care for their symptoms prior to the survey, the majority of them were men. Among the prevalent cases who had sought prior care for their respiratory symptoms, 80% of them had not been diagnosed with TB before the survey. Of those who provided a reason for not seeking

### 2017 PATIENT PATHWAY ANALYSIS

#### 2017 WHO GLOBAL TB REPORT

### 2016 INVENTORY STUDY (1/2)

Subcounty	Population	Estimated TB cases	Estimated TB deaths
1	100,000	1,000	100
2	150,000	1,500	150
3	200,000	2,000	200
4	250,000	2,500	250
5	300,000	3,000	300

In the subcounties sampled, 715 of 3409 smear-positive TB cases in laboratory registers were not found in TIBU. The estimated level of under-reporting of smear-positive TB cases in Kenya was

### 2013 HEALTH EXPENDITURE UTILIZATION SURVEY

12.7% of patients reported some sickness but did not seek care, down from 22.8% in 2003. Nearly 40% of these people reported that they did not consider their illness serious enough to seek care.

## PEOPLE WITH TB IN THE SYSTEM, NOT NOTIFIED OR DX

### Presenting to health facilities, not diagnosed

- Only 43% of people who seek care are likely to visit a health facility with capacity for DS-TB diagnosis on their first visit to the health care system. Even fewer are likely to receive a DR diagnosis on their first visit.
- Among bacteriologically confirmed cases, 5% were on current TB treatment, 24% had a past history of TB treatment, and 71% had no history of TB treatment. Among the prevalent cases who had sought prior care for their respiratory symptoms, 80% of them had not been diagnosed with TB before the survey.

### Diagnosed, not notified

- The estimated level of under-reporting of smear-positive TB cases in Kenya was 20.7% (95%CI 18.4–23.0). In the subcounties sampled, 715 of 3409 smear-positive TB cases in laboratory registers were not found in TIBU.
- Under-reporting was greatest in high TB burden subcounties (23%) and lowest in low TB burden subcounties (13%). The highest level of under-reporting occurred in the Nairobi region (33%), while the lowest occurred in the North Eastern region (12%).
- The gap between prevalence and notification rates is higher among males, age groups 25-34, and the older age group of 65 years and above.
- In 2016 the ratio of children under 5 to children aged 5-14 years was 1.0:1.0 which is lower than the expected range of 1.5-3:1 indicating that there is under-diagnosis and/or under-reporting in this age group.

### Diagnosed by private sector, not notified

- 41% of people initiate their care seeking journey in private (formal or informal) facilities.
- Diagnostic capacity exists in the private sector, however notifications from the private sector only account for 12% of the estimated burden.
- In multivariable analysis, unreported cases were significantly more likely to have been diagnosed at a private facility (aOR 2.6, 95%CI 1.8–3.9).

### Diagnosed by public sector, not notified

- 58% of people initiate their care seeking journey in public facilities.
- Diagnostic capacity exists in Levels 2-5 of the health care system, and notifications from the public sector accounted for approximately 47% of the estimated burden.
- 84.5% of total cases found in the study were coming from public health facilities.
- Of those unreported cases, 81% were coming from public health facilities.

## 2017 PATIENT PATHWAY ANALYSIS

Note: The PPA was completed based on 2016 data so may differ from data presented in the 2017 WHO report

- Only 43% of people who seek care are likely to visit a health facility with capacity for DS-TB diagnosis on their first visit to the health care system. Even fewer are likely to receive a DR diagnosis on their first visit.
- 41% of people initiate their care seeking journey in private (formal or informal) facilities.
- Diagnostic capacity exists in the private sector, however only notifications from the private sector only account for 12% of the estimated burden.
- 58% of people initiate their care seeking journey in public facilities.
- Diagnostic capacity exists in Levels 2-5 of the health care system, and notifications from the public sector accounted for approximately 47% of the estimated burden.

NO DATA ENTRY HERE								

Proportion of TB prevalence across subnational geographic areas  
(Applicable if prevalence survey is designed to have sub national point estimate)

KNCV  
TUBERCULOSIS FOUNDATION

# Workshop aims and steps:

Consensus on evidence [potentially pre CWS?]

Problem Prioritization (“which are the biggest problems?”)

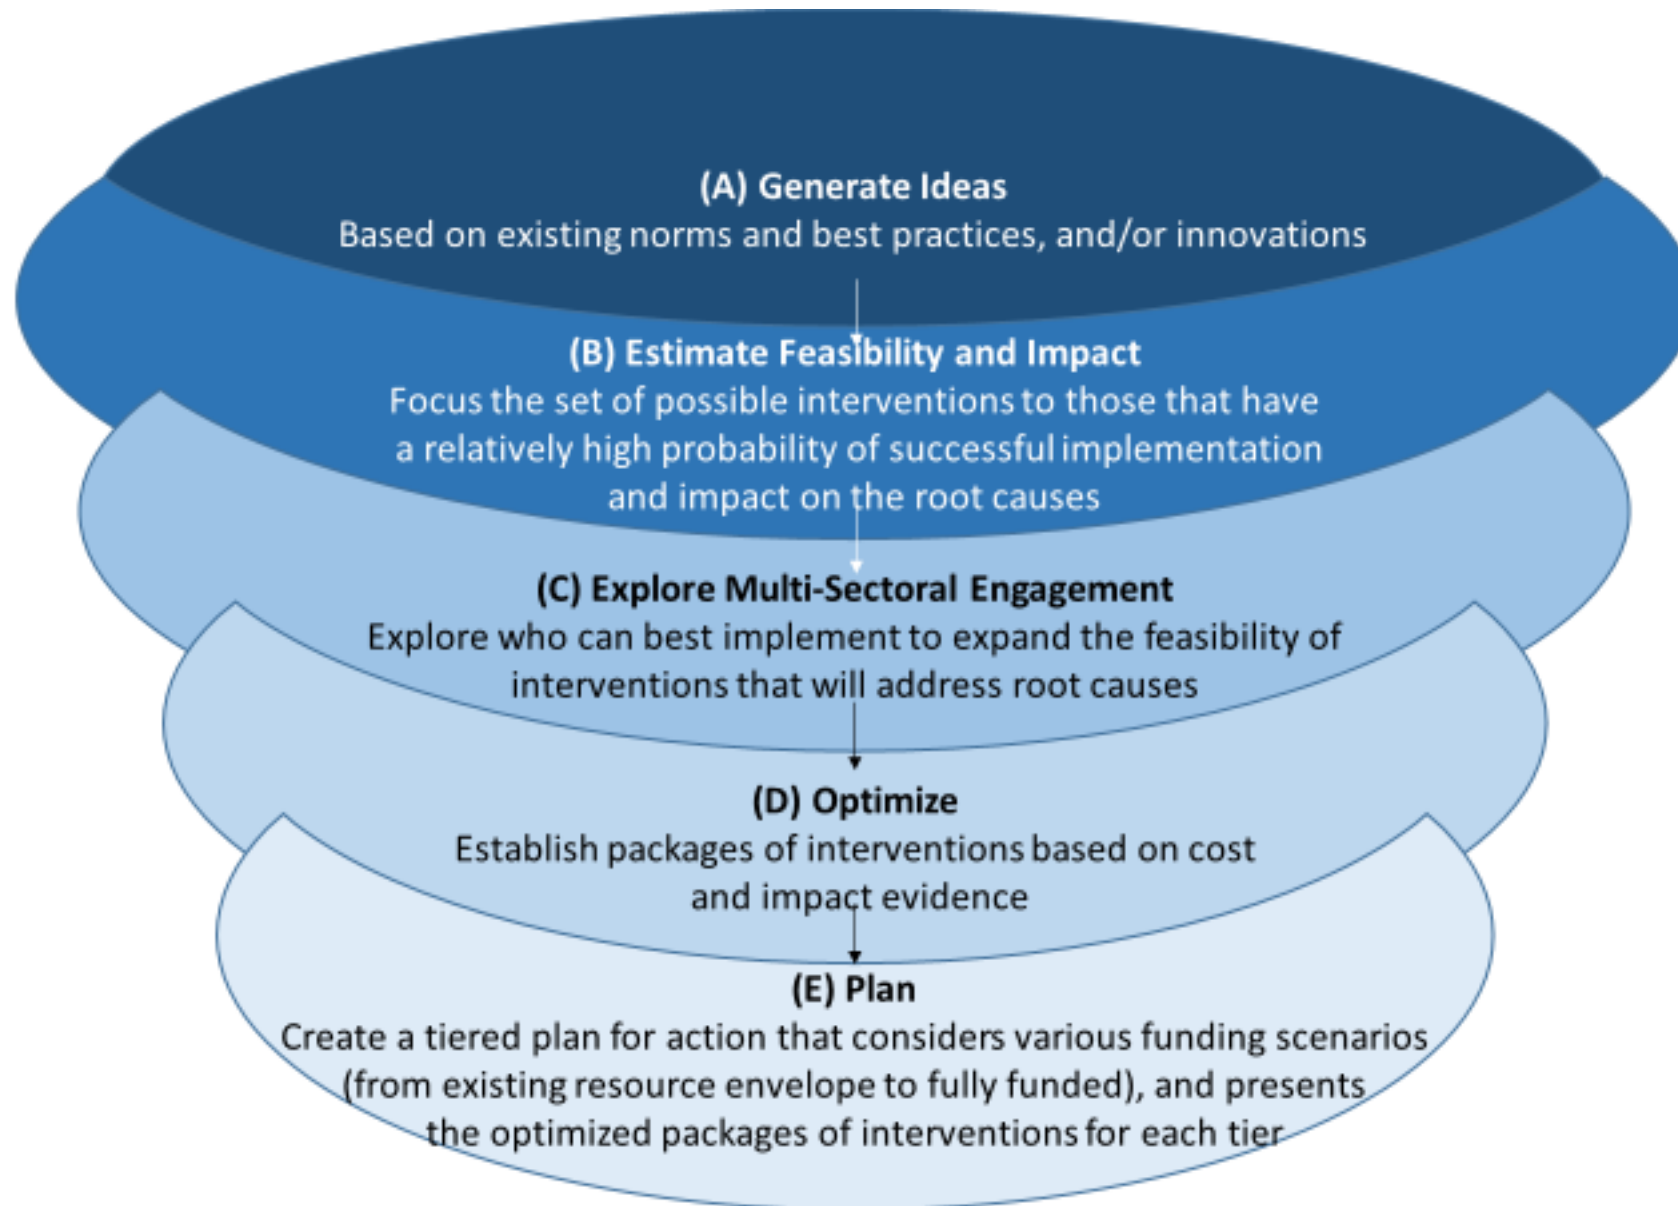

Root cause analysis (“what causes/ contributes to these problems?”)

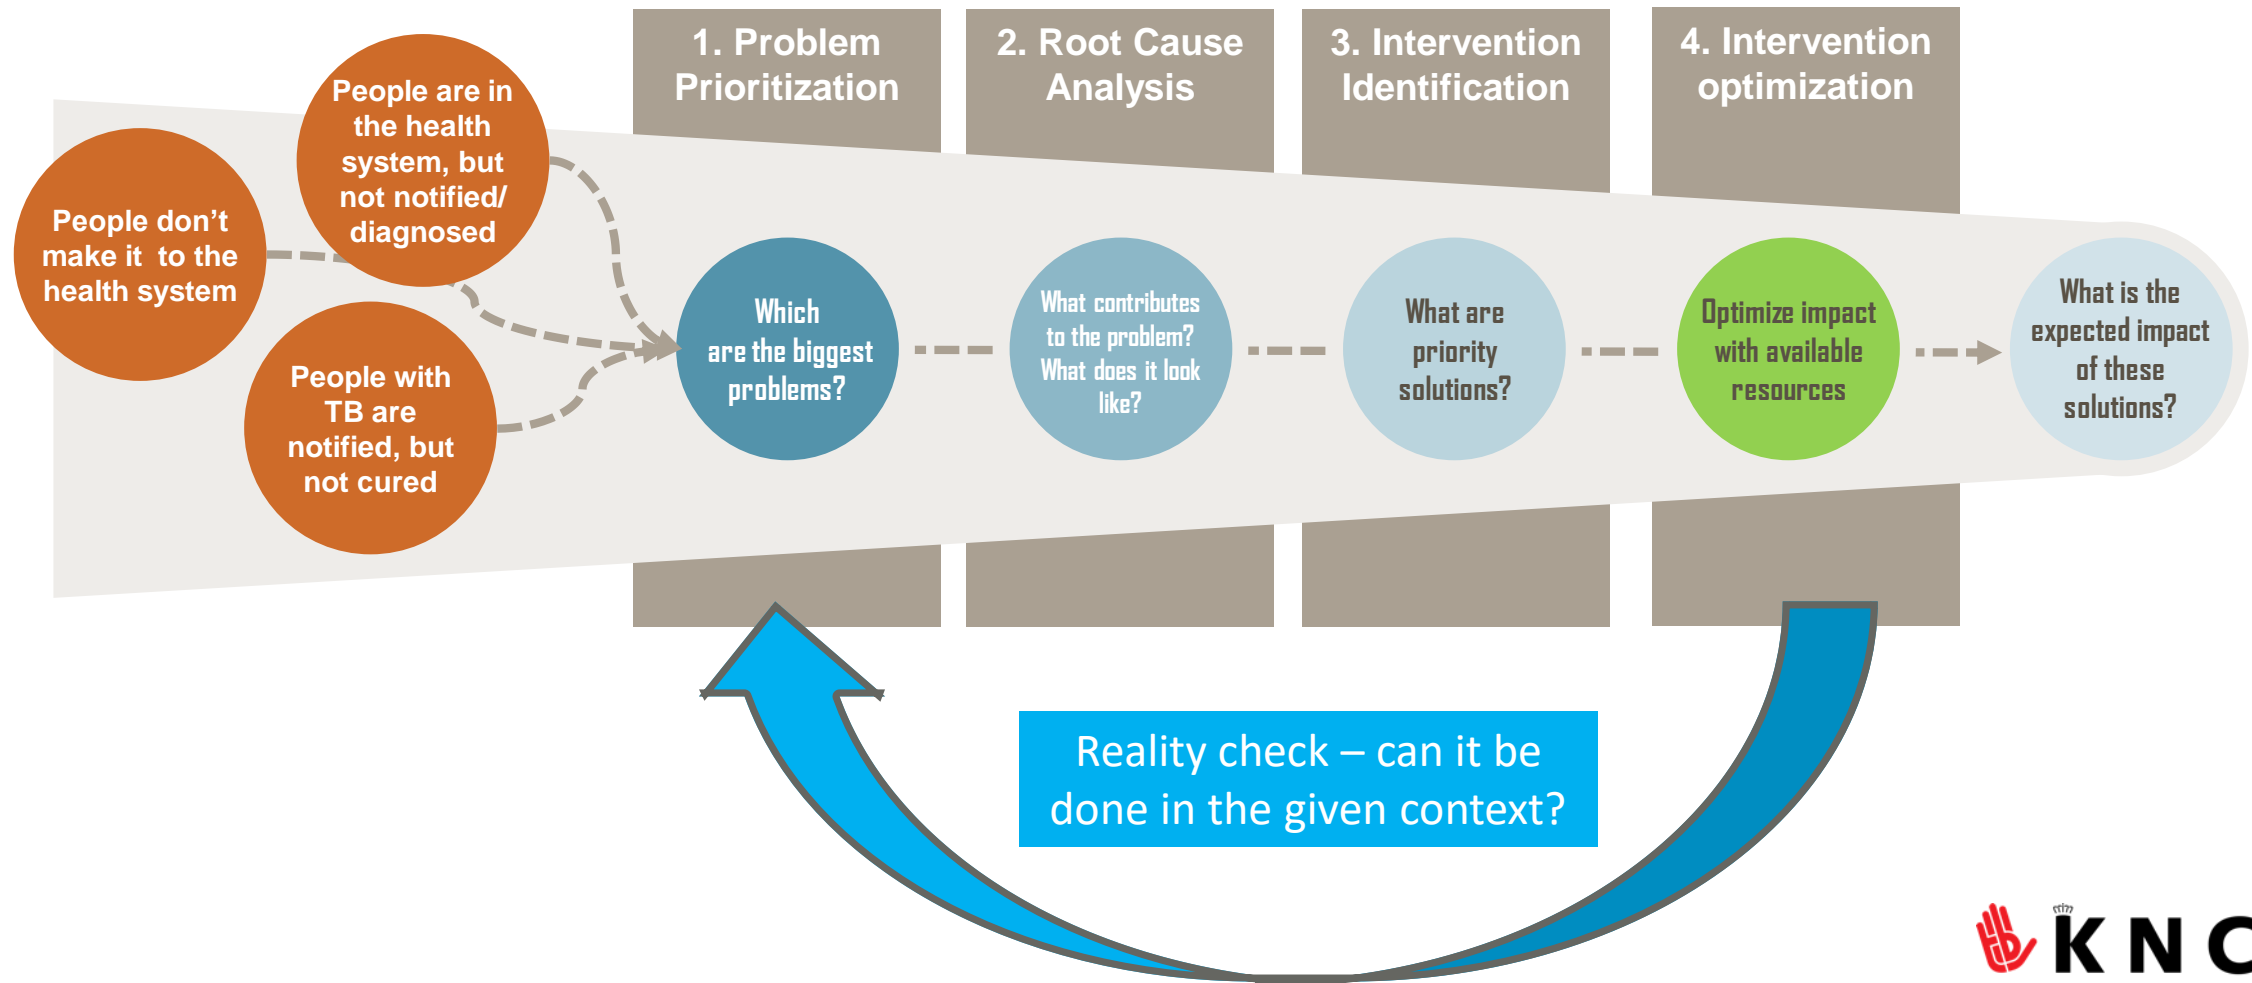

Intervention optimization (“what are priority solutions to optimize impact?”)

- *Intervention identification* (“what needs to be/ can be done?”)
- *Intervention optimization* (“what works best vs what can we afford?”) - [“best guess”, impact modelling, economic evaluation]
- *Intervention allocation* (“who and where?”)

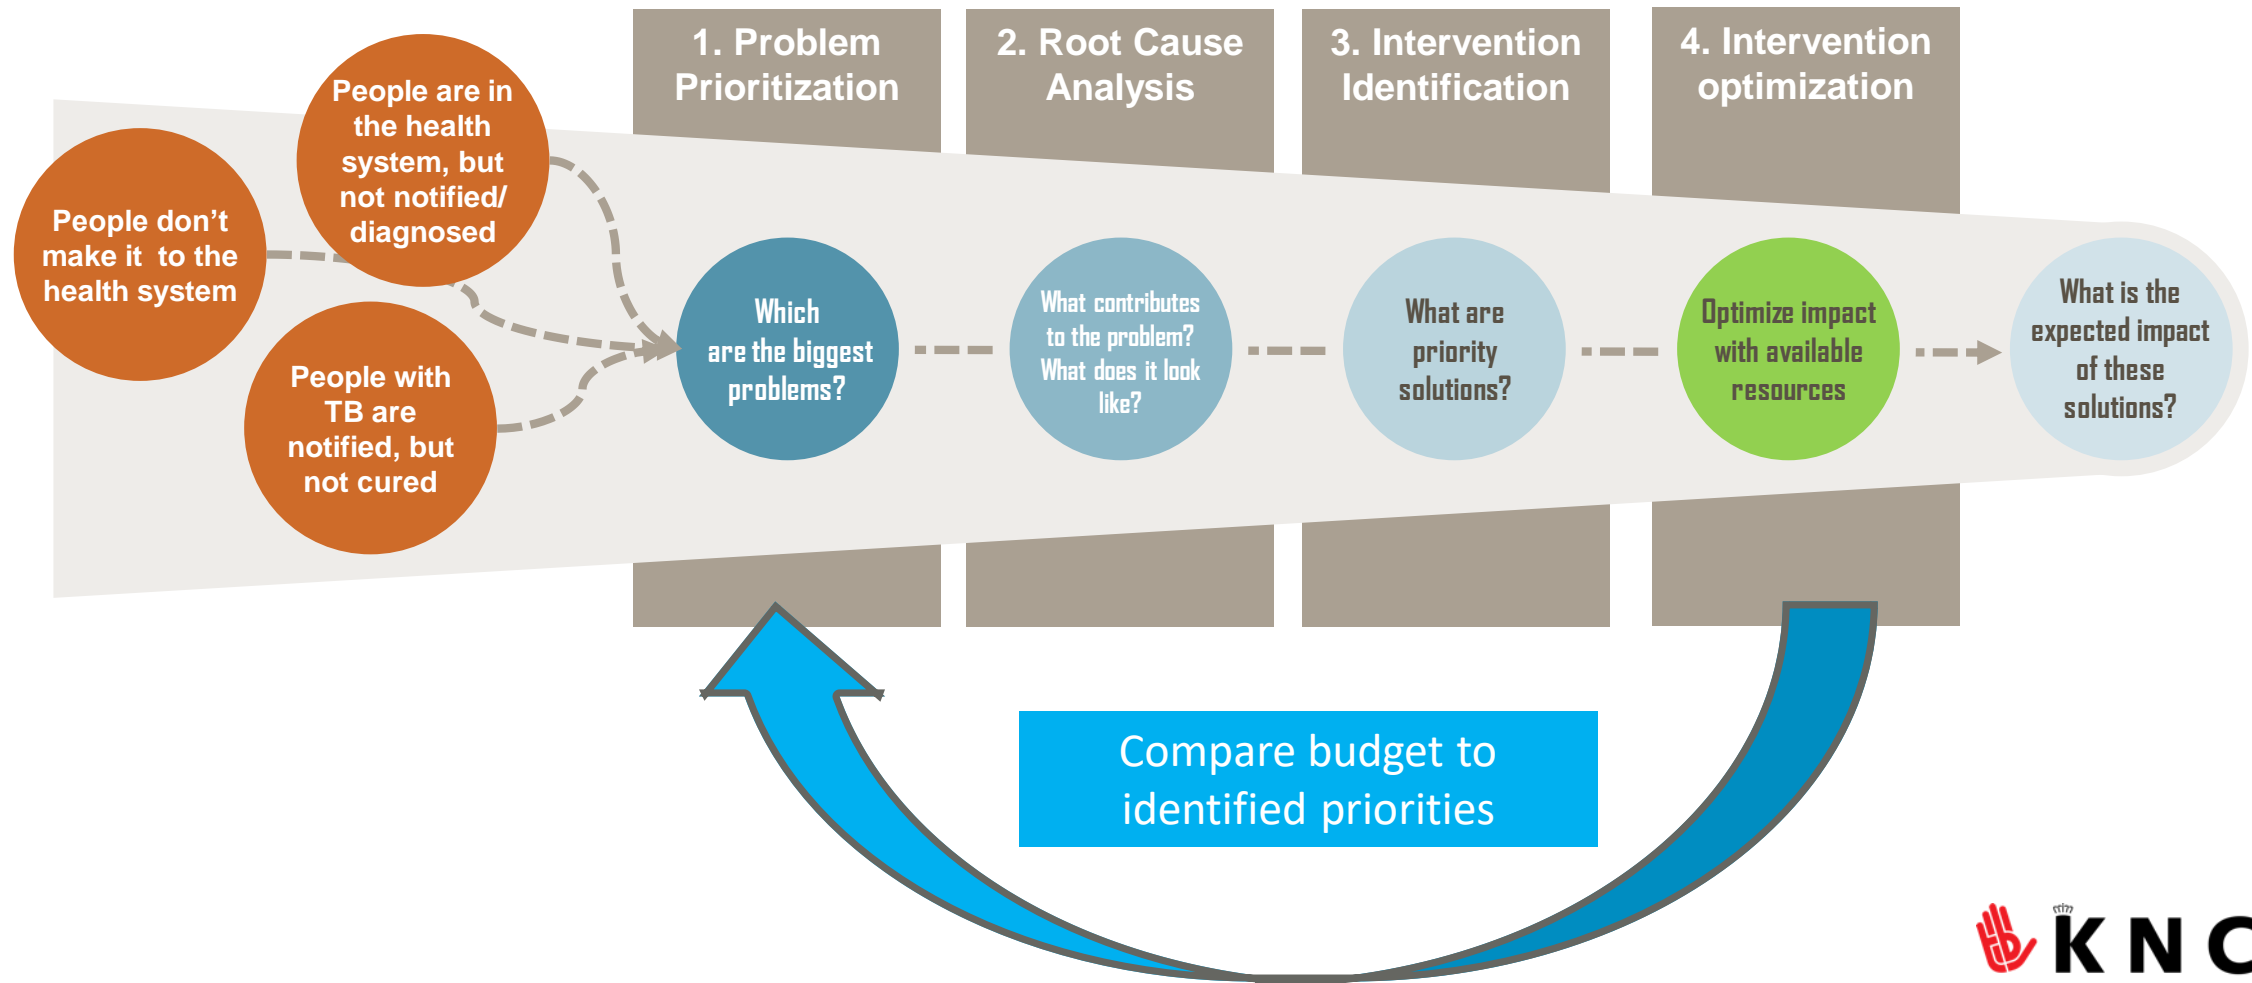

# Intervention optimization

“What is feasible?”

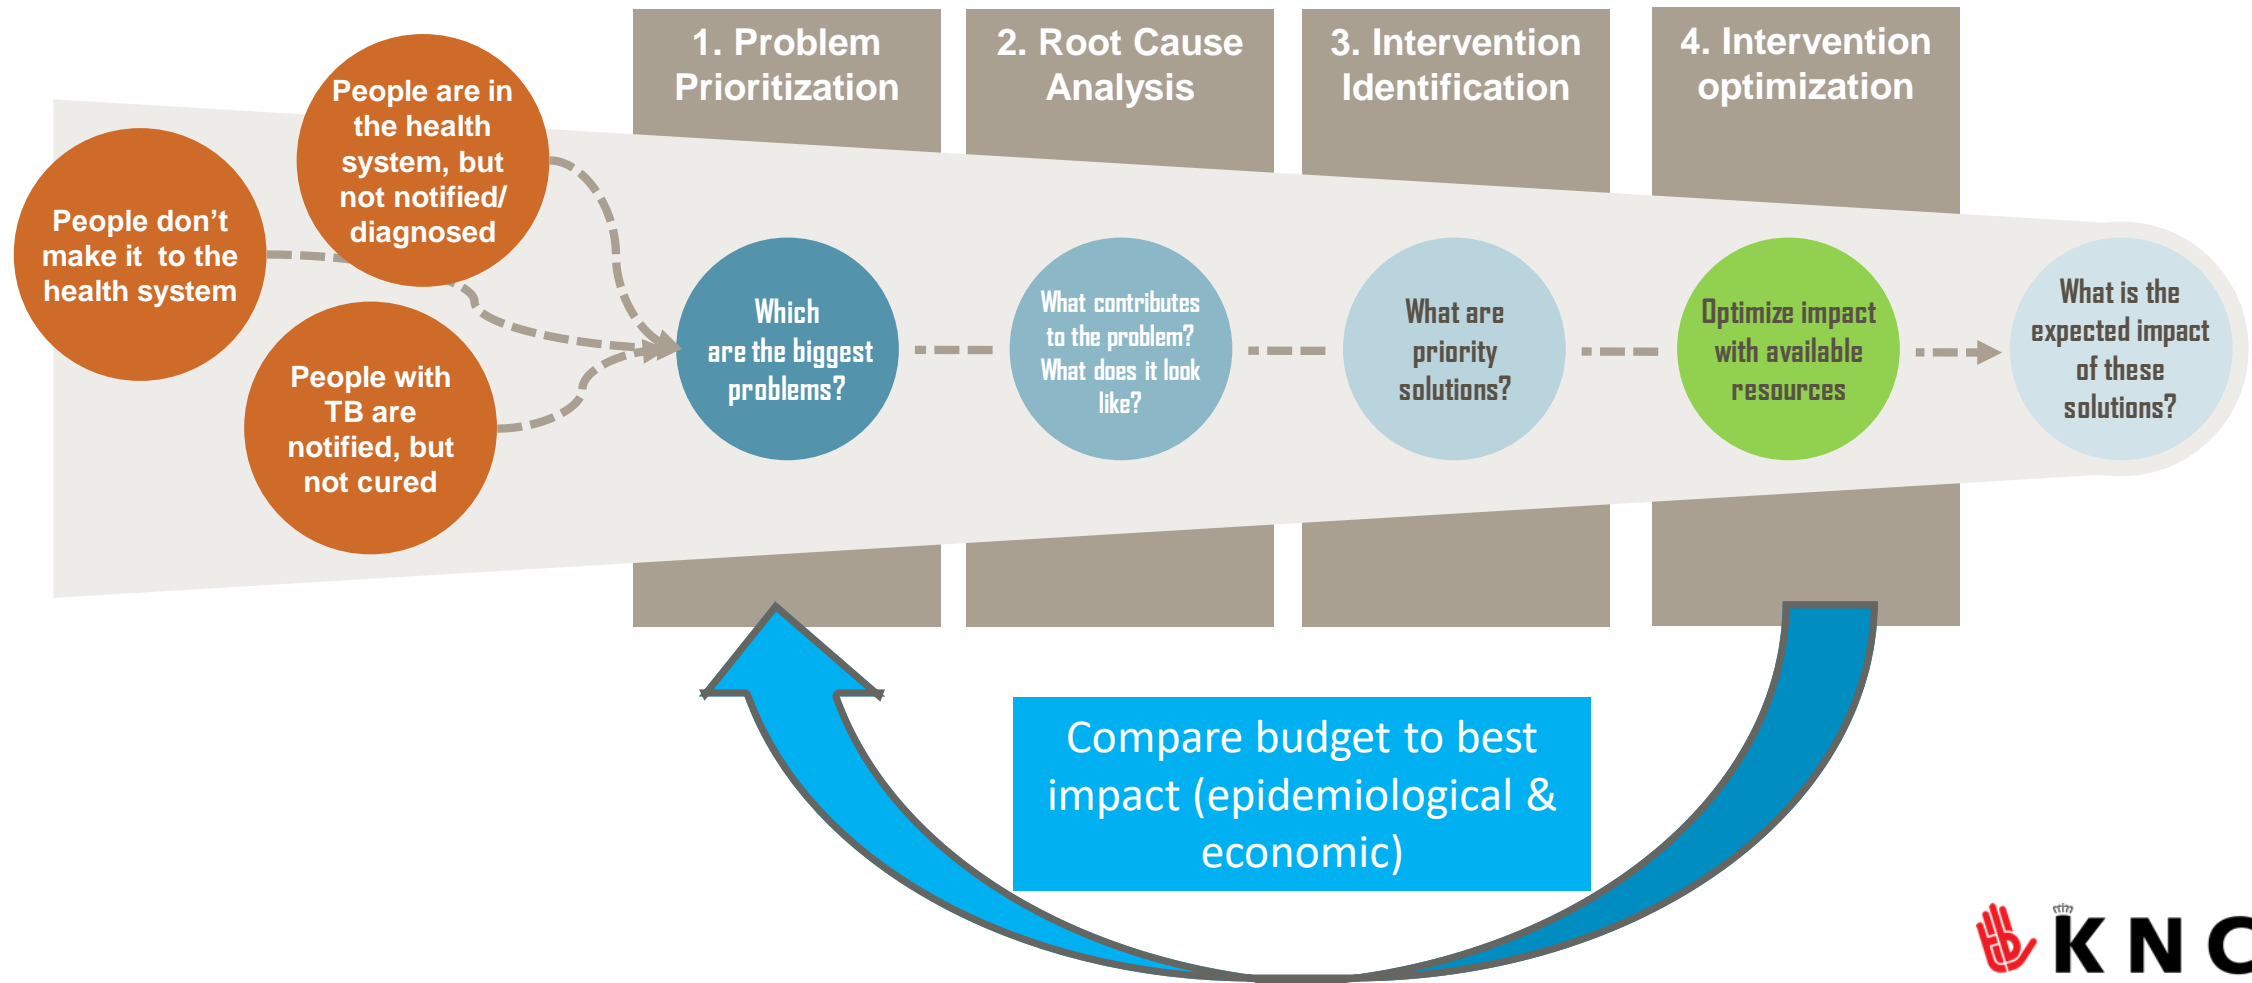

# Intervention optimization

“What can we afford?”

# Intervention optimization

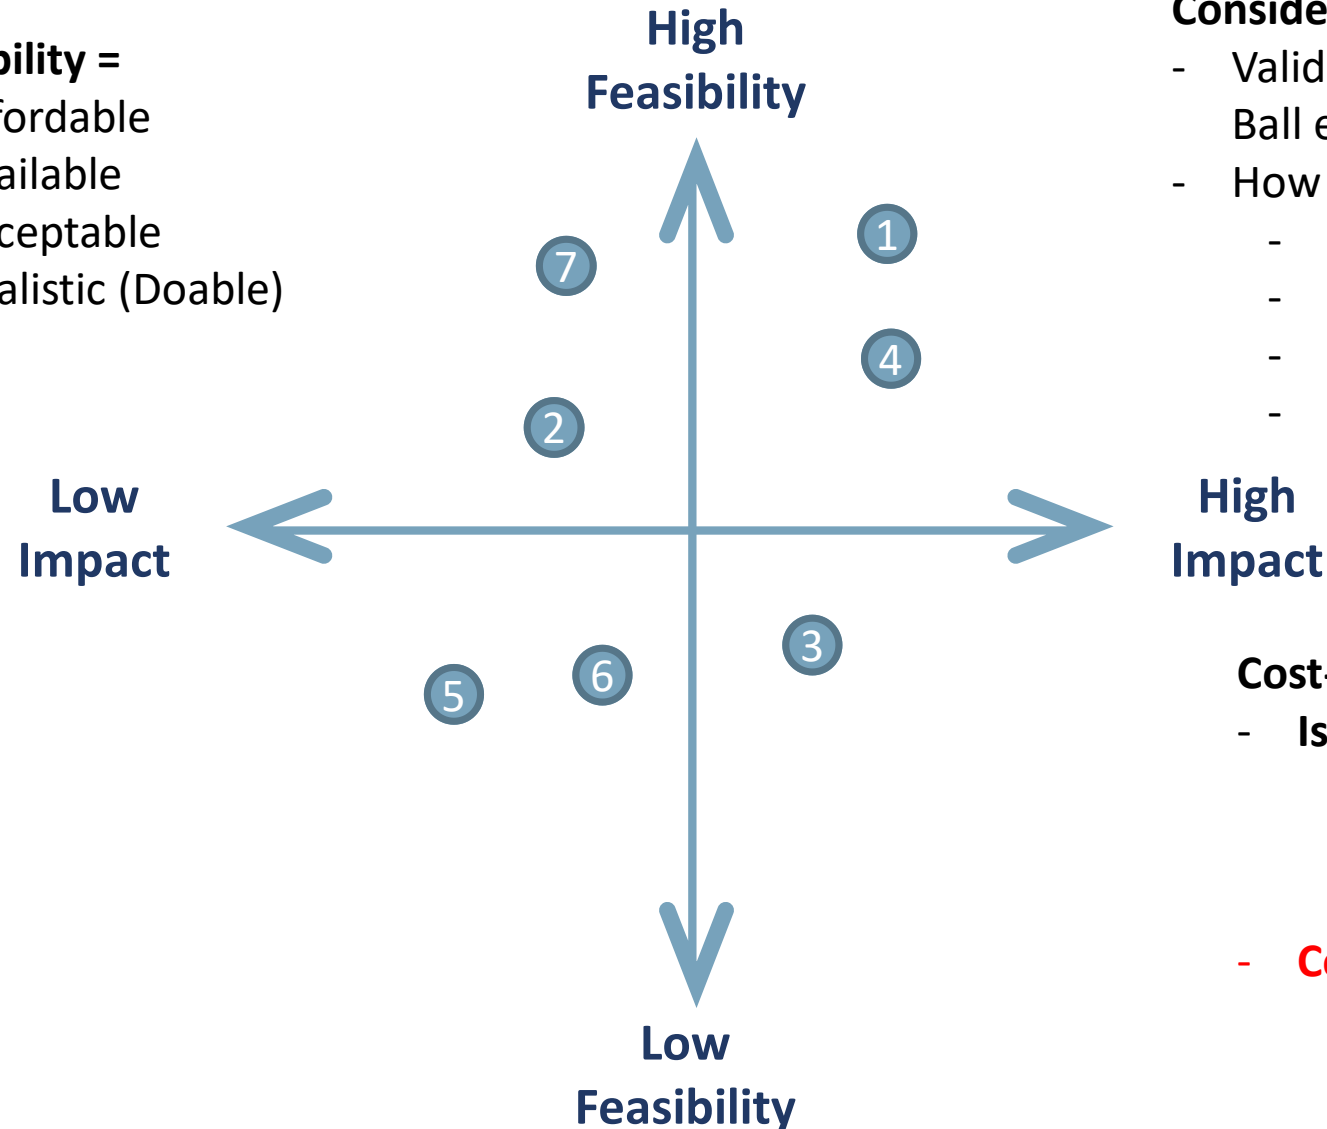

“What makes most sense?”

# Modelling to support prioritisation/optimisation

## Feasibility =

- Affordable
- Available
- Acceptable
- Realistic (Doable)

## Considerations for impact modelling:

- Validation/ robustness/ limitations? (avoid crystal Ball effect)
- How to address complexity?
  - Intervention packages vs interventions
  - Strategies depending on available resources
  - Short-term vs long-term vision
  - Intervention interdependency (A before B)

## Cost-effectiveness:

- **Is it worth the effort?**
  - Short-term and long-term gains
  - ICERs
  - “Business case”....
- **Costing vs economic evaluation!**

# To be discussed:

- Agree on: “Essential”(Core), “Optimal”(Supplementary) and “Additional”(Optional) Data/Evidence
- “Automation” is preferable to manual extraction and analysis
  - *PPA wizard and KNCV data consolidation and visualization tool*
  - *Integration into routine surveillance systems is preferable => will transform a “one-off” into responsive, continuous monitoring system (and make it easier on repeat)*
- Create data consolidation logic => if there is no obvious issue, do we need the data (dig deeper)?

# Discussion points continued

- Can we model and compare completely different or multiple strategies? – where are the limits?
- How do we account for environmental changes and subnational differences?
- How and when to bring the different elements and partners together (analysis, planning, modelling, economic evaluation)?
- When is added value achieved (thresholds) and how do we measure this? (%)
- **Expectation management!** (NTPs, donors, partners)
